Studies were conducted to evaluate the biology and ecology of wild radish as well as its glucosinolate production and its weed management possibilities. Wild radish emerging in fall months formed a rosette of leaves which aided its winter survival. Plants emerging from December through March that did not form a rosette had minimal survival.

By analyzing wild emmer wheat at the Evolution Canyon microsite, a hot spot of sympatric speciation, we highlighted how disruptive ecological selection drives primary sympatric speciation in situ. Natural selection, overruling the homogenizing effects of gene flow, split the metapopulation of wild emmer wheat into three reproductively isolated populations.

Faculty research in the Department of Biology and Wildlife spans the breadth of the biological sciences, from molecular biology to ecosystem science. Investigating emerging viral pathogens, microbes that detoxify environmental contaminants, the molecular genetics of obesity and diabetes, impacts of climate change on polar organisms and ecosystems, and more, our faculty work alongside graduate, undergraduate and high school students to address key issues of vital interest to Alaska and beyond.

The homologous genes that overlapped between wild mice and humans included genes that have been associated with traits related to host immunity and obesity in humans. Gene-bacteria associations identified in both humans and wild mice suggest some commonality to the host genetic determinants of gut microbial composition across mammals.

A large portion of the total forest ecosystem biomass resides in the living fungi, which rapidly die and recycle their nutrients to the soil (Fogel 1980). This great fungal component not only recycles nutrients but also captures significant amounts of forest nutrients, which reduces leaching loss from the system.
